

Migratory Adaptive User Interfaces

Takuto Yanagida and Hidetoshi Nonaka

Laboratory of Intelligent Information Systems, Division of Computer Science,
Graduate School of Information Science and Technology, Hokkaido University

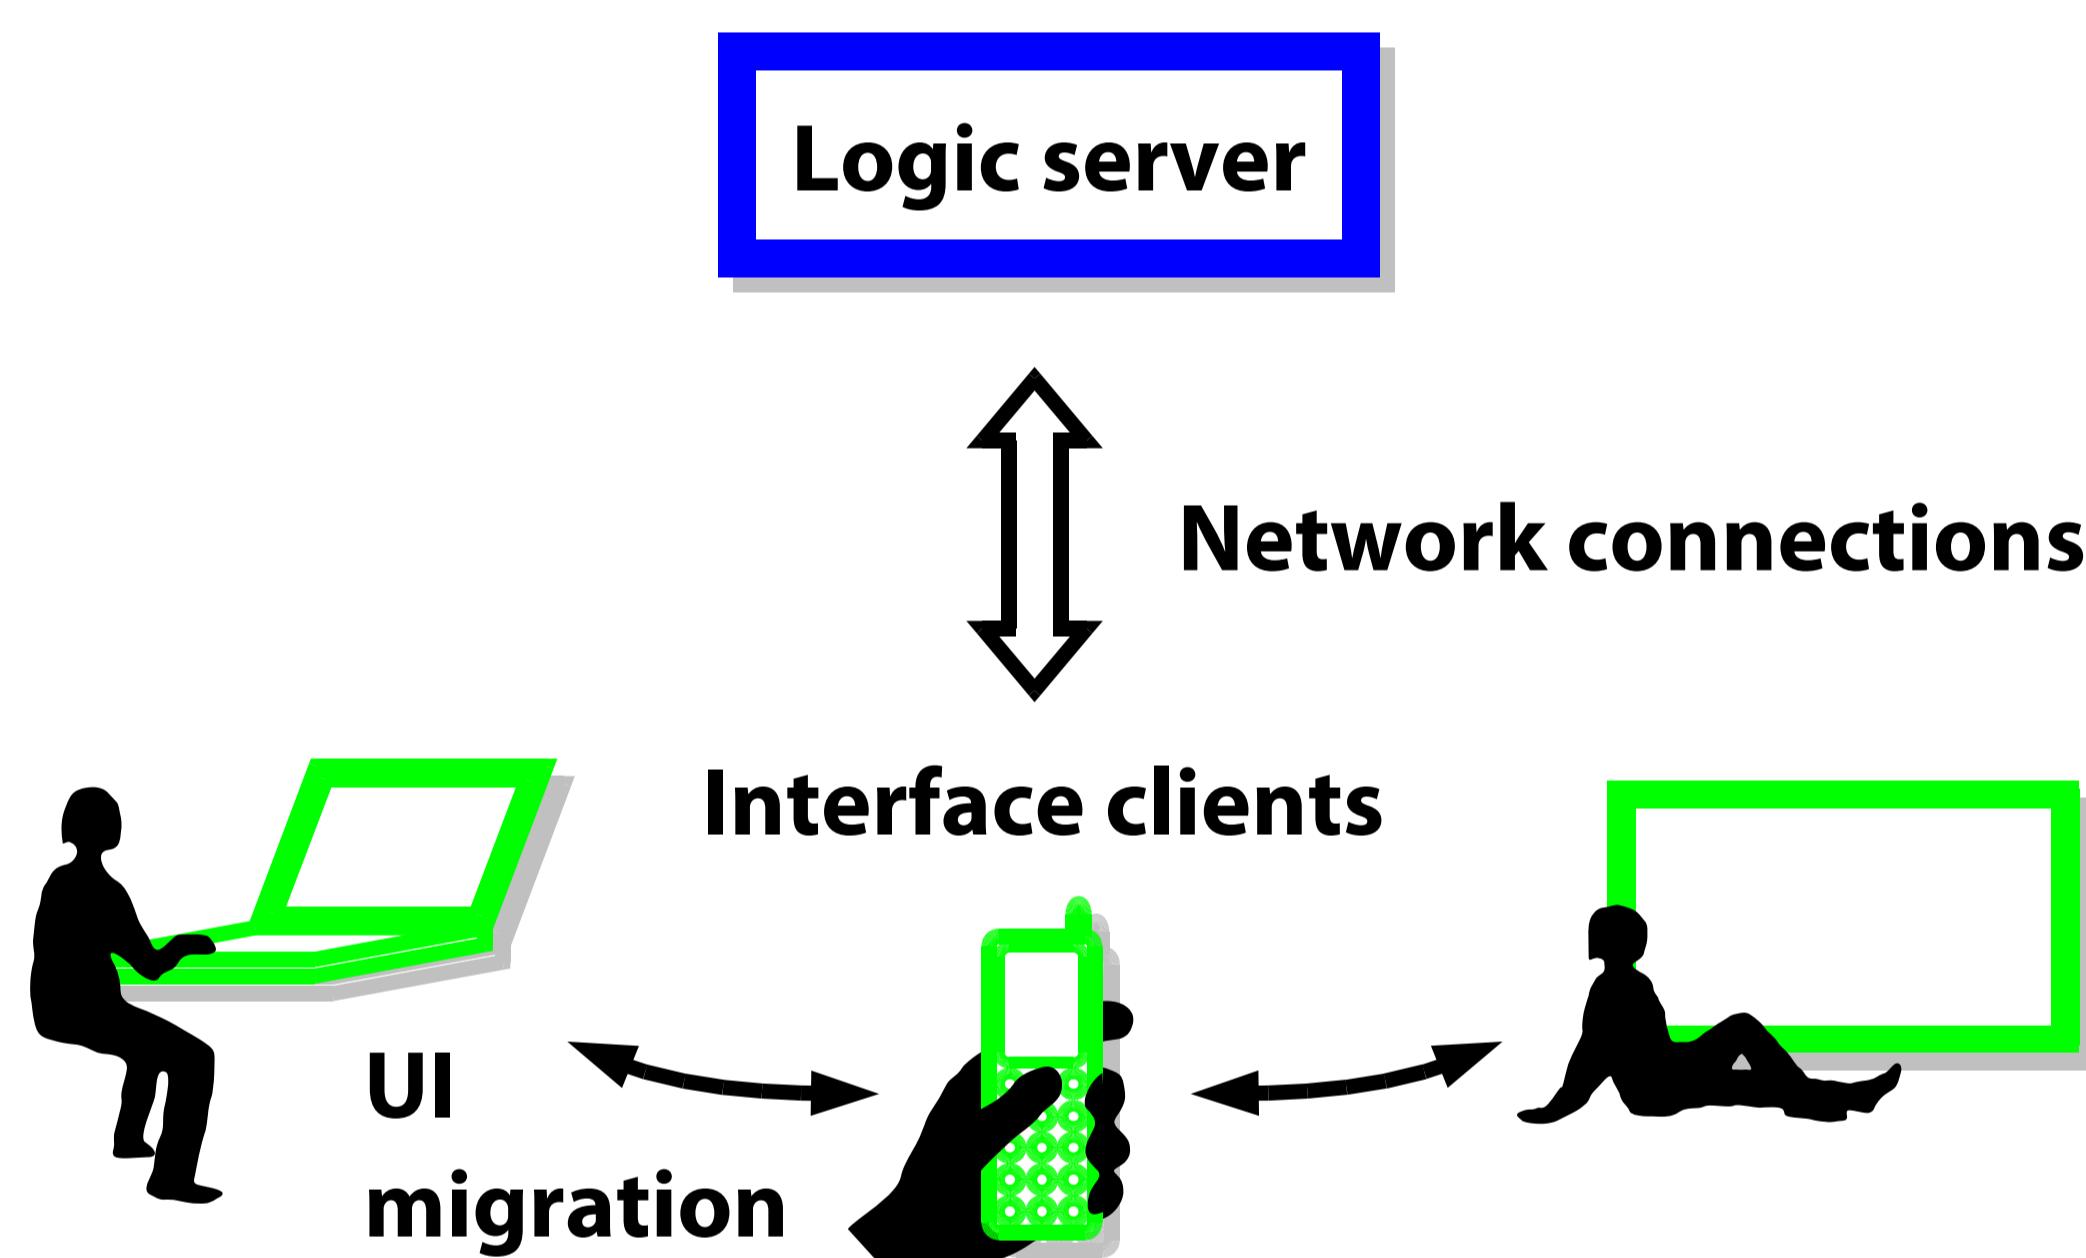

Demands

Constant improvements of technology have brought a large variety of platforms, and have made **users' new demands** about for interactive services:

- **To use services through different devices and modalities** depending on their use contexts.
- **To change devices and take their tasks from one to another**, which is called **user interface (UI) migration**.

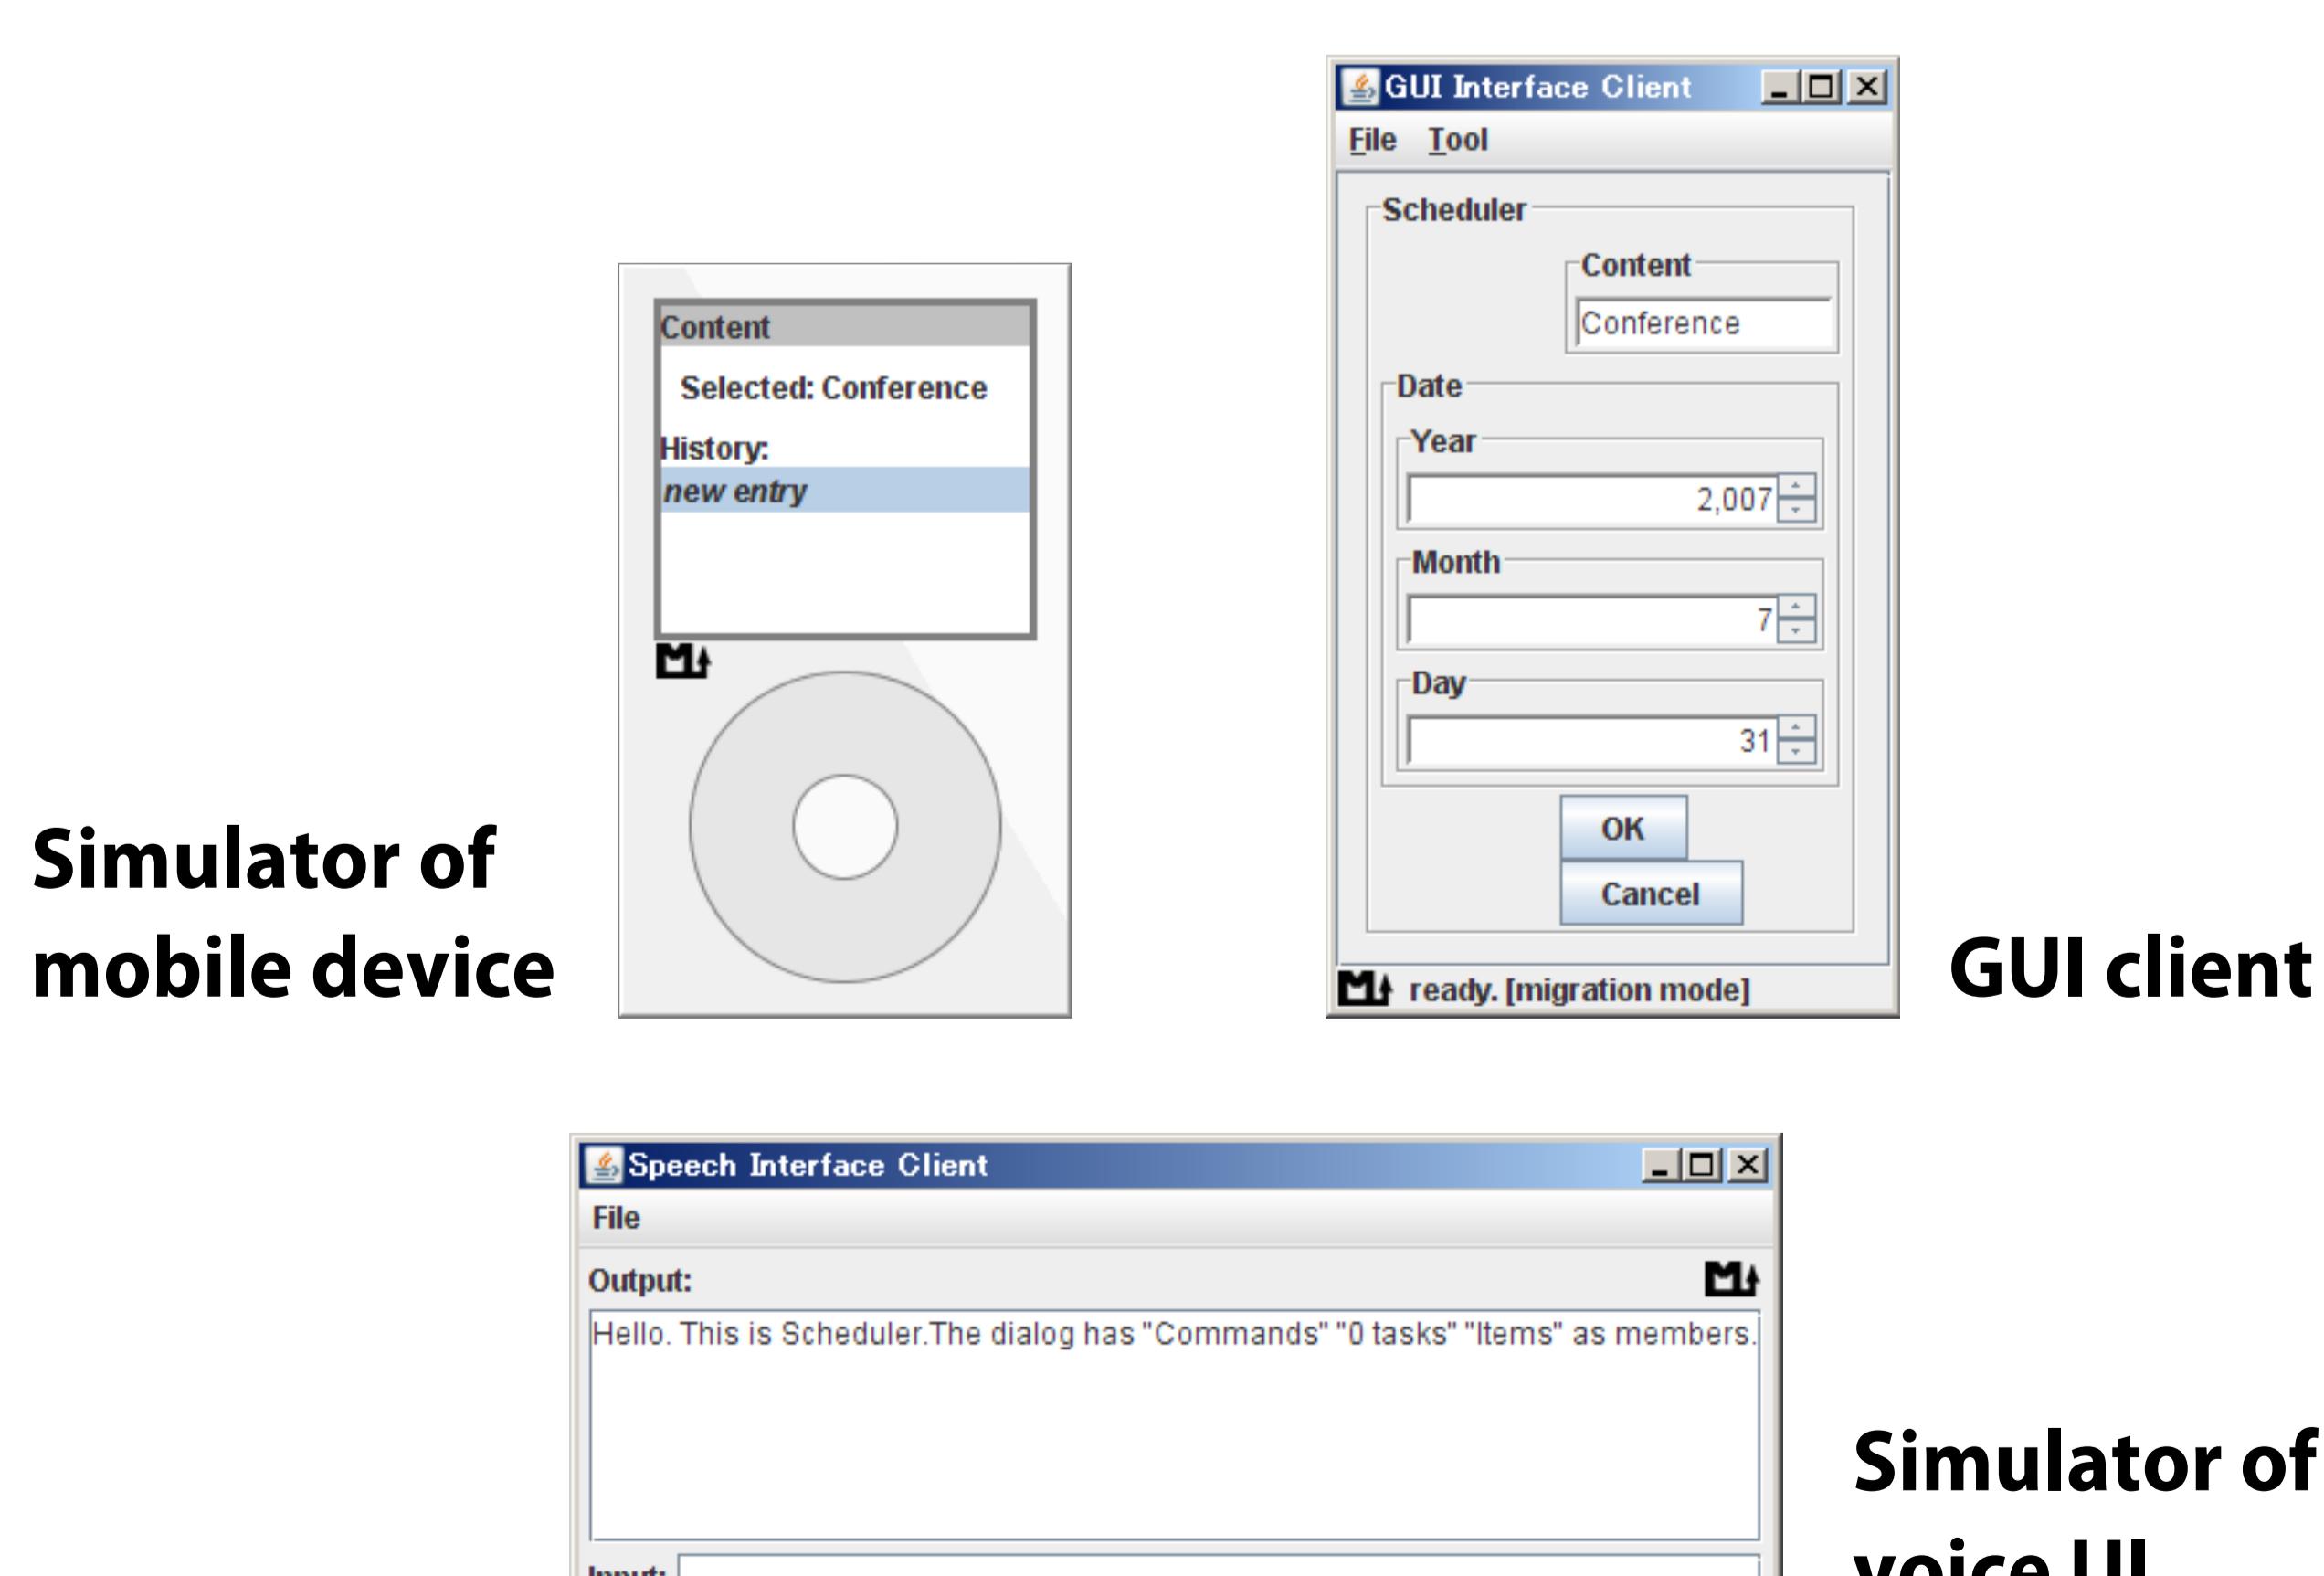

Our UI architecture, **Interface client/ logic server (ICLS)** is:

- targeting **dialog-based interactive services** like web applications,
- supporting **UI migration** and the simultaneous use of multi devices,
- offering **adaptive UIs** for devices and services with **declaration of meanings** in logical descriptions.

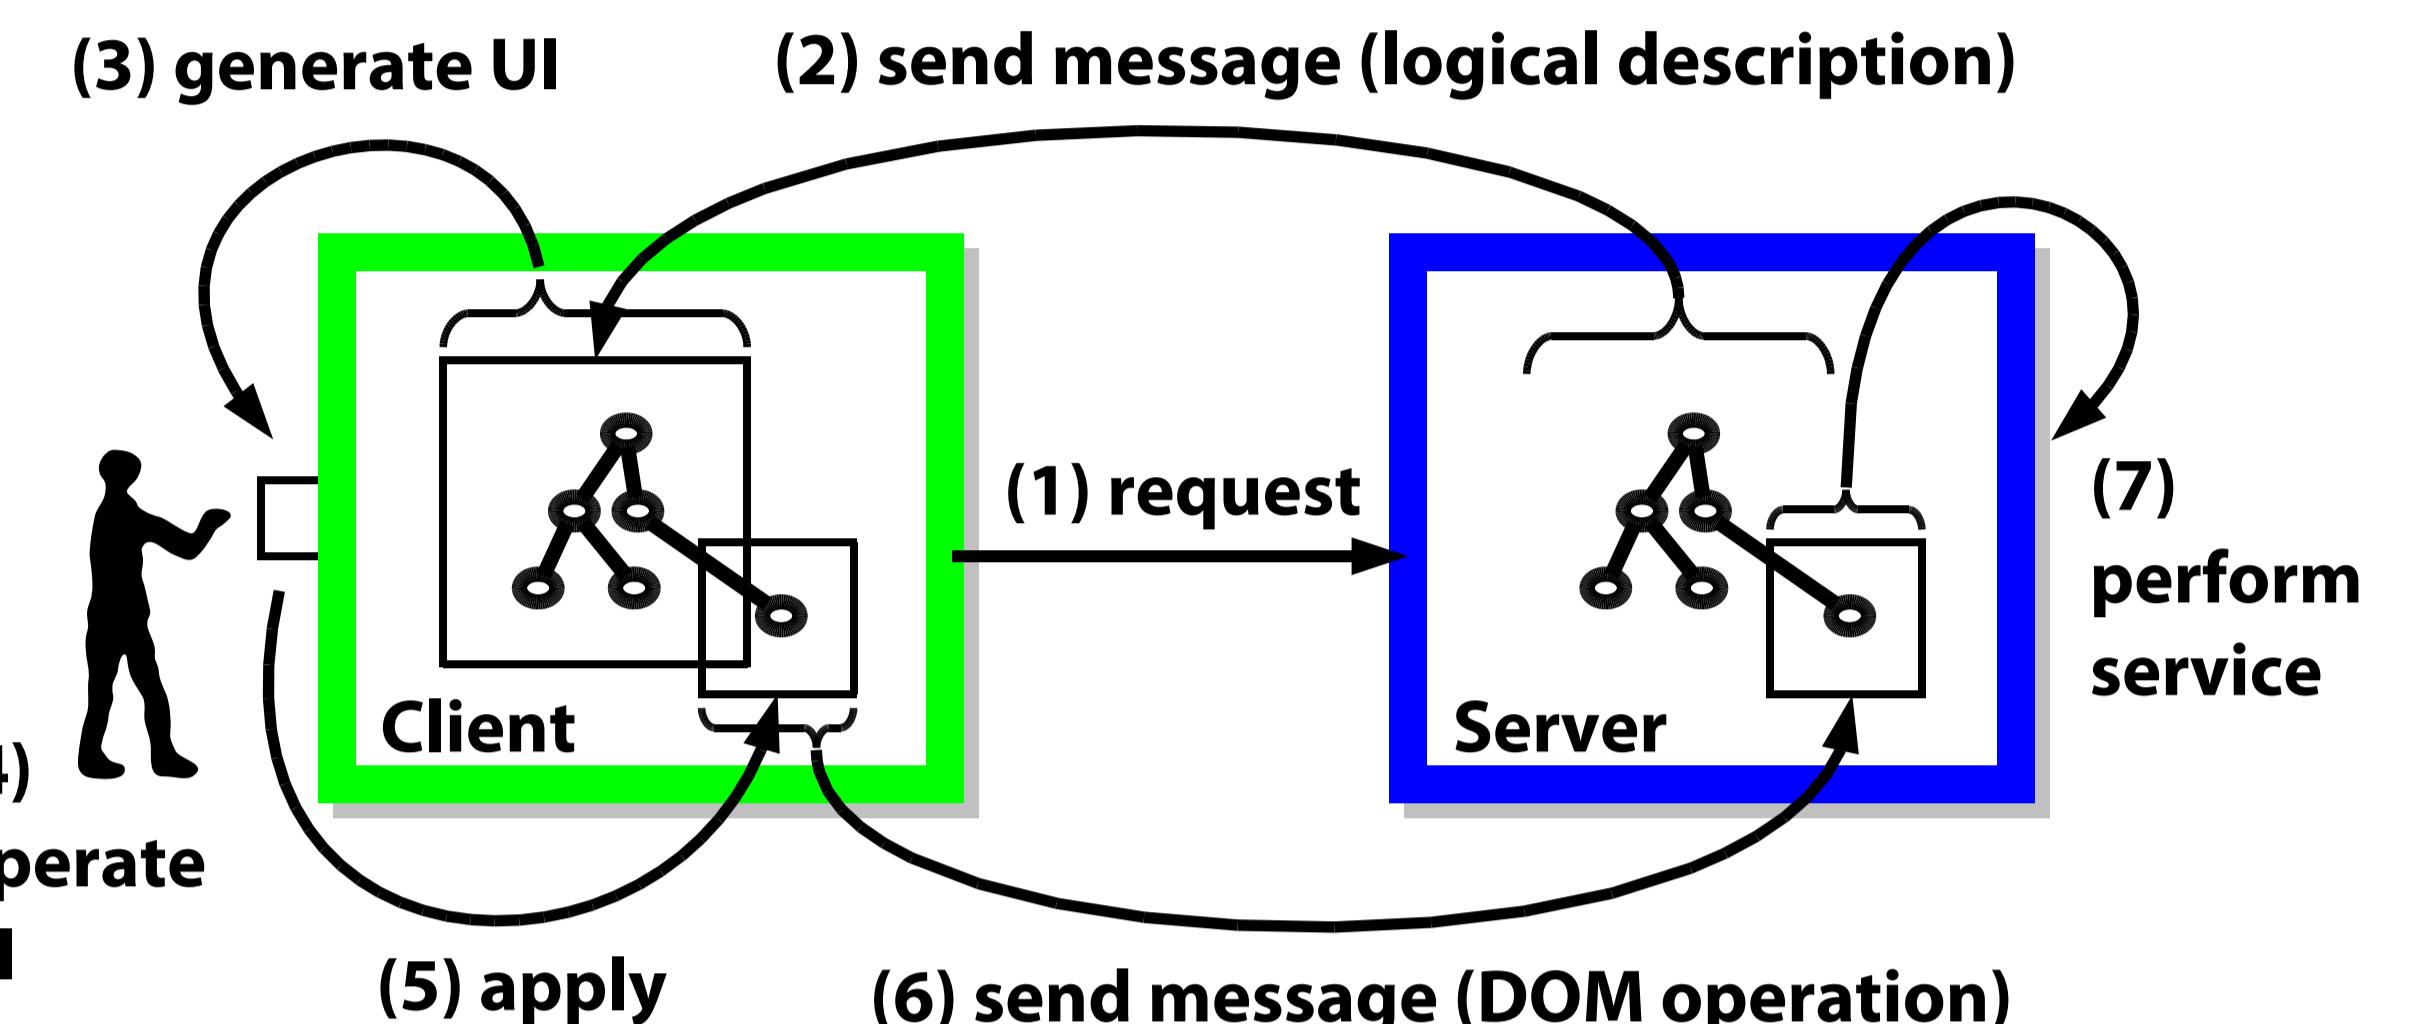

Implementations

We implemented ICLS as a framework, which is a **class library written in Java language (JDK 1.6) with a semantic web library Jena**. In order to verify the feasibility of the ICLS specification and the stability of the communication protocol, we developed three interface clients and two logic servers.

Architecture

1. A session of a service starts by a **request** from a client to a server.
2. After that, the client **receives a logical description** from the server.
3. The client constructs DOM tree, and **generate a UI** based on the tree.
4. After the UI generated on the client, the user can **operate the UI**.
5. The client **changes the DOM tree** corresponding to the user's UI operations.
6. The client **sends this DOM changes** as messages to the server.
7. The server **performs the service** according to the message from the client.

Logical Description

We use XML documents written in **abstract interaction description language (AIDL)** as logical descriptions of UIs. In AIDL, arbitrary UI structures and their **current state (meaning the history of users' operations)** are described as **selection acts**, which represent essential function of UI elements, and are grouped composing an **interaction tree**.

Selection acts consist of three elements:

- a **type** (a set of choices),
- a **meaning** (a purpose in a service),
- a **state** (a current state).

We introduce one of semantic web technologies, **resource description framework (RDF)** for expressing meanings of interactions on certain services with RDF classes.
